(54) Process and electromagnetically coupled plasma apparatus for etching oxides

(57) Described is an apparatus (10) for producing an electromagnetically coupled plasma comprising a chamber (12) having a dielectric shield (18) in a wall (16) thereof and a planar coil (20) outside of said chamber (12) coupled to a radio frequency source (30), whereby a scavenger (26) for fluorine is mounted as a solid article said chamber (12). When a silicon oxide is

etched with a plasma of a fluorohydrocarbon gas, the solid fluorine scavenger (26) reduces the free fluorine radicals, thereby improving the selectivity and anisotropy of etching and improving the etch rate while reducing particle formation.

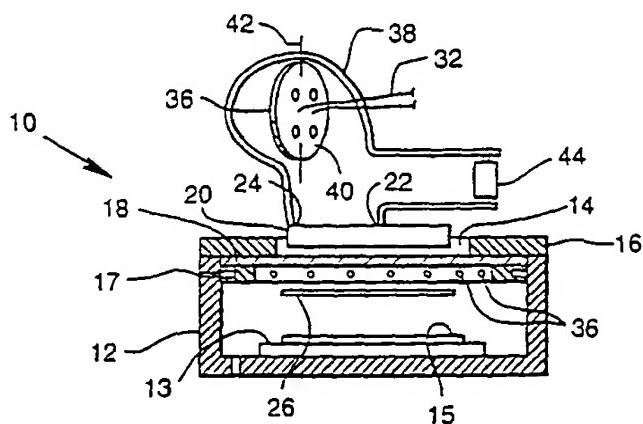

Fig. 1

EP 0 802 560 A1

tuted for a silicon plate. Again, the thickness of the carbon-containing article must be small as compared to the skin depth of the applied RF power at the temperature of use. If the fluorine scavenger source is located outside of the plasma region, it can be heated to a temperature that will pass free silicon or carbon atoms into the plasma. In such case a means of heating the silicon or carbon source can also be provided.

In a further preferred embodiment the spacing between the dielectric window and the substrate is large, so that diffusion of active plasma species to other parts of the chamber can occur and the fluorine scavenger is placed in a ring around the substrate. In this case, the RF induction field need not penetrate the solid fluorine scavenger, and the requirement of large RF skin depth in solid fluorine scavengers, as described hereinabove, is not required. Other variations of placement and materials will suggest themselves to one skilled in the art and are to be included herein.

According to a specific aspect, the invention relates to an apparatus for producing a planar plasma comprising a chamber having a dielectric window at one end thereof, a port for plasma precursor gases to be fed to said chamber, and a substrate support within said chamber for holding a generally parallel to said access port, an electrically conductive planar coil outside said chamber and proximate to said dielectric window and means for coupling a radio frequency source to said coil, the improvement which comprises providing solid source for a scavenger for fluorine in or near the plasma generated in said chamber.

According to another specific aspect, the invention relates to a method for processing a substrate containing an oxygen-containing layer thereon comprising mounting said substrate in a vacuum chamber fitted with a dielectric shield so that said substrate is essentially parallel to said shield, applying a radio frequency bias to the substrate, introducing a fluorohydrocarbon etch gas to said chamber, forming a plasma from said gas by applying a radio frequency current to a substantially planar coil located outside of said chamber proximate said dielectric window, and introducing solid source for a scavenger for fluorine into said chamber, thereby etching the oxygen-containing layer selectively with respect to a non-oxygen-containing layer on said substrate.

Claims

1. An apparatus for plasma etching a substrate comprising a chamber including an inlet for a plasma precursor etch gas and a substrate support for the substrate:
and a ring of silicon or carbon-containing material mounted about the substrate. 55
2. An apparatus according to claim 1 wherein said ring supplied ions into said plasma that enhances selectivity between oxygen-containing and non-oxygen-containing surfaces.
3. An apparatus according to claim 1 or 2 wherein said plasma precursor etch gas includes fluorine.
4. An apparatus according to claim 3, wherein said ring provides a scavenger for fluorine into said plasma.
5. An apparatus according to any of claims 1 to 4 wherein the scavenger ring is of silicon.
- 10 15
6. An apparatus according to any of claims 1 to 5 further comprising a heater for controlling the temperature of the ring.
7. An apparatus according to claim 5 wherein the heater heats the temperature of the ring above the ambient processing temperature.
- 20
8. An apparatus according to any of claims 1 to 7 wherein an RF power source is coupled to said ring.
- 25
9. An apparatus according to claim 5 wherein the temperature of the ring of silicon is such that silicon atoms are generated that can pass into the plasma.
10. An apparatus according to any of the preceding claims further including a capacitive electrode.
- 30
11. An apparatus according to any of the preceding claims further including an external antenna for inductively coupling energy into said chamber.
- 35
12. An apparatus according to claim 11 wherein said external antenna is parallel to said substrate support.
- 40
13. A plasma etch apparatus especially according to any of the preceding claims including a chamber into which RF energy may be coupled to maintain a plasma within said chamber;
a source of plasma precursor etch gas including fluorine;
- 45
- a substrate support within the chamber for supporting a substrate to be etched in a generally horizontal position;
- a ring of a silicon-containing or carbon-containing solid material about the substrate support; and
- a heater for said ring so as to provide silicon or carbon atoms to the plasma to scavenge fluorine.
- 50

and extends across the access port 14. The dielectric shield 18 is sealed to the upper wall 16 to define the vacuum sealable chamber 12. The chamber 12 also has a port 17 for admittance of plasma precursor gases to the chamber 12.

A planar coil 20 is disposed within the access port 14 adjacent to the dielectric shield 18. The coil 20 is formed as a spiral having a center tap 22 and an outer tap 24. The plane of the coil 20 is oriented parallel to both the dielectric shield 18 and a support 13 for a wafer 15 to be processed in the chamber 12. The coil 20 is thus able to produce a planar plasma within the chamber 12 which is parallel to the wafer. The distance between the coil 20 and the support surface 13 is usually in the range from about 3-15 cm and can be adjusted. A scavenger for fluorine, illustrated as a silicon article 26, is situate between the support surface 13 and proximate to the dielectric shield 18. Thus the fluorine scavenger is in or near the generated plasma.

Referring now to Figs. 1 and 2, the planar coil 20 is driven by an RF generator 30 of the type which can operate at a frequency in the range from about 100 kHz up to 100 MHz, and preferably at less than or equal to about 13.56 MHz. The output of the generator 30 is fed by a coaxial cable 32 to a matching circuit 34. The matching circuit 34 includes a primary coil 36 and a secondary loop 38 which may be positioned to allow effective coupling of the circuit and for loading of the circuit at the frequency of operation. The primary coil 36 may be mounted on a disk 40 which can rotate about a vertical axis 42 to adjust the coupling. A variable capacitor 44 is in series with the secondary loop 38 to adjust the circuit resonant frequency with the frequency output of the RF generator 30. Impedance matching maximizes the efficiency of power transfer to the planar coil 20. Additional capacitance 46 may be provided in the primary circuit to cancel part of the inductive reactance of the coil 36 in the circuit.

An RF bias power can be applied to the substrate via the substrate support 13 when etching oxides in the chamber 12. A second RF signal may be passed from the RF bias 30 or a separate RF source (not shown) may be connected to the substrate support 13. The walls of the chamber 12 act as the grounded electrode in that case. Another alternative is to use the planar coil, or the silicon or other solid fluorine scavenger article as a counterelectrode. The RF bias power controls the substrate sheath voltage.

Referring now to Fig. 3, the planar coil 20 induces an electromagnetic field which penetrates the dielectric shield 18 and has a field strength profile 60 as shown in broken line. The uniform electromagnetic field provides a uniform circulating field of electrons in the electromagnetic field region which impact the precursor gas molecules, creating plasma species within the plasma region. Because there will be little or no impact on the substrate in the non-planar direction, except as deliberately caused with RF bias power, the reactive plasma species will cause little damage to the wafer.

A fluorine scavenger, when it is a solid article, should be situate above and parallel to the surface being etched and adjacent to the dielectric shield for maximum effectiveness and good uniformity over large substrates, such as 200 mm diameter silicon wafers. When it is a solid article, such as silicon plate 26, the fluorine scavenger must be placed and sized so that it will not interfere with the RF induction field generated through the dielectric shield. This can be done by considering the thickness of the solid article, its resistivity as a function of temperature and the frequency of the RF power to be inductively coupled to the coil. The RF power frequency and the article thickness and resistivity must be chosen so that at the highest solid article operating temperature, when its resistivity is lowest, the skin depth of the RF electromagnetic field in the fluorine scavenger is large with respect to the article thickness. Typically this requires a low frequency, less than 13.56 MHz operation, with, for example, thin silicon plates of less than several millimeters thickness. The resistivity of the solid scavenger source also can be varied, such as by providing a doped silicon plate, because the dopants will decrease the silicon resistivity at operating temperatures of up to several hundred degrees centigrade. In order to provide process stability, temperature control of the scavenger source can also be provided.

According to the present invention the scavenger source is provided as a solid article, said article having the shape of a plate, a ring or a cylinder.

However, in a preferred embodiment the solid scavenger source is a ring.

In an especially preferred embodiment the fluorine scavenger is placed in a ring around the substrate.

The plasma etching process is predicated on the fact that when a fluorhydrocarbon precursor gas is exposed to a plasma generating field, various fragments are generated, including F, CF and CF₂ radicals. The free fluorine etches oxides such as silicon oxide, but other species form C-F polymers, generally containing about 50% of fluorine, that can deposit onto the sidewalls of the etched via and also act to protect underlying and overlying layers from being etched. However, this polymer is attacked by oxygen, generated by the silicon oxide, and also by free fluorine, and thus the selectivity between silicon oxide and other materials on the substrate being etched is not high. However, when a scavenger for fluorine is provided in the plasma, such as a silicon source, the scavenger takes up free fluorine, thus reducing attack of the substrate by free fluorine. Further, when fewer free fluorine radicals are present in the plasma, the protective polymer becomes carbon-rich, e.g., contains only about 40% by weight of fluorine.

The scavenger for fluorine can most easily be provided in the form of a solid silicon article, e.g., a plate or slice, in or near the plasma.

Compounds of carbon are also suitable scavengers for fluorine.

A solid carbon-containing compound such as graphite or silicon carbide can also be used and substi-

Description

This invention relates to a process and apparatus for etching oxides in an electromagnetically coupled planar plasma apparatus.

US-A-4,948,458 to Ogle describes an apparatus for producing planar plasmas that can operate over a wide pressure range. The apparatus is a vacuum chamber having a dielectric window or shield in one wall of the chamber. A planar coil, outside of the chamber and proximate to the dielectric shield, and an RF source is coupled to the coil. The chamber is also fitted with a port for the inlet of plasma precursor gases into the chamber, and a port for ingress and egress of a substrate to be processed, as well as a support for the substrate parallel to the dielectric window. When an RF current is applied to the coil, a changing magnetic field is induced which extends inside the chamber through the dielectric shield, inducing a circular flow of electrons within the processing region of the chamber. This induced circular electric field is substantially in a plane parallel to the planar coil, which reduces the transfer of kinetic energy in the non-planar direction. The substrate to be etched is also mounted in the direction of the plane of the plasma and thus the velocity component of charged particles in the non-planar direction with respect to the substrate during processing is minimized, and the treatment on the substrate is generally limited to the chemical interaction of the plasma species with the substrate, except in the case where RF bias is applied to the substrate with respect to a grounded electrode or chamber. The entire disclosure of US-A-4,948,458 is incorporated herein by reference.

The above plasma reactor is useful for etching materials such as aluminum, but it has limitations with respect to etching oxides such as silicon oxide, which are required in the manufacture of semiconductor devices. Silicon oxide films and layers, for example, are applied to various substrates during the manufacture of silicon devices, including silicon, metal layers, silicon nitride and the like. Typically a photoresist is deposited over the silicon oxide layer to be etched and patterned, and the silicon oxide etched with a fluorohydrocarbon gas such as CF_4 , C_2F_6 , C_3F_8 , CHF_3 and the like. For example, a via in a silicon oxide layer over polysilicon may be etched and the via later filled in with a conductor to make contact between the underlying polysilicon and a conductive layer overlying the silicon oxide. In order to fill in vias, which are becoming smaller and deeper, the etch process has several stringent requirements; the sidewalls of the vias must be straight (anisotropic etch) and the etching must be selective with respect to the overlying photoresist layer and the underlying material, i.e., the etch process must etch the silicon oxide layer at least at a faster rate than overlying and underlying layers, and preferably the selectivity should be higher than about 10:1. For other semiconductor devices and arrays, large and small features are present and must be etched at the same time, requiring that large and

small features in the same material, e.g., silicon oxide, be etched at the same rate, i.e., without microloading. Microloading for purposes herein is defined as

$$1 - \frac{\text{etch rate small features}}{\text{etch rate large features}}$$

still further, since silicon oxide layers are generally quite thick, high etch rates are also desirable, particularly when single wafer processing is being performed (as opposed to batch-type processing) to permit high throughput.

15 The etch reactor of Ogle, while useful to etch conductive metal layers, cannot meet the above-described etch requirements for oxides such as silicon oxide. In general silicon oxide is etched with fluorine-containing etch gases, as noted above. Silicon oxide is etched with poor selectivity; using gases with a high C:F ratio, or gases containing hydrogen raises selectivity but sacrifices etch rate and produces tapered profiles and micro-loading. Thus merely increasing the carbon:fluorine ratio of the etch gas, or increasing the gas flow rates, increases the taper of the sidewalls, increases micro-loading and reduces the etch rate. Fluorohydrocarbon etch gases in addition form polymeric solids that can form particles which deposit on the substrate, causing contamination of the substrate during the etch process.

Accordingly, it is an object of the invention to provide improved etching of oxide films or layers in the above-described electromagnetically coupled planar plasma equipment.

This object is solved by the apparatus and reactors for planar plasma etching of independent claims 1, 13, 14, 19 and 22 and by the method of independent claim 23. Further advantageous features, aspects and details of the invention are evident from the dependent claims, the description and the drawings. The claims are intended to be understood as a first nonlimiting approach of defining the invention in general terms.

The addition of a scavenger for fluorine as a solid article, especially a ring in the electromagnetically coupled planar plasma apparatus improves the etching of oxides with fluorohydrocarbon etchants with respect to the selectivity of etching of the oxide, gives improved anisotropy and improved etch rates.

Fig. 1 is a cross sectional view of such apparatus for plasma treatment.

Fig. 2 is a schematic illustration of the circuitry for the apparatus of Fig. 1.

Fig. 3. is a schematic view illustrating the electromagnetic field profile produced by the apparatus of Fig. 1.

A plasma treatment apparatus will be further described with reference to Fig. 1. A plasma treatment apparatus 10 suitable for etching single semiconductor wafers includes a vacuum chamber 12 having an access port 14 in an upper wall 16 of the chamber 12. A dielectric shield 18 is disposed below the upper wall 16.

14. A plasma etch apparatus especially according to any of the preceding claims comprising

a planar electrode external to said apparatus for supplying energy to form a plasma within said apparatus.

a substrate support in said reactor for supporting a substrate to be etched generally parallel to said electrode.

an inlet for a plasma precursor gas comprising fluorine, and

a solid ring including carbon or silicon about the substrate support for scavenging fluorine.

15. The apparatus according to claim 14 characterized in that said apparatus is a reactor.

16. A reactor according to claim 14 further including a heater for said solid ring.

17. A reactor according to claim 15 or 16 wherein said reactor has a dielectric window spaced from and parallel to said substrate support.

18. A reactor according to claim 15 to 17 wherein an RF power source is connected to said solid ring.

19. A plasma reactor especially according to any of claims 15 to 18 including

an inlet for passing a plasma precursor gas into said chamber, said plasma precursor gas including fluorine that generates oxide etching and polymer forming species in said plasma that provide selectivity between oxygen-containing and non-oxygen-containing surfaces,

a support for a substrate to be etched in said plasma, and

a ring of a fluorine scavenger about said support to supply fluorine scavenging to said plasma.

20. A reactor according to claim 19 wherein said ring is heated to activate the scavenger.

21. A reactor according to claim 20 wherein said solid scavenger is a ring of silicon.

22. A plasma etch chamber including

a plasma etch gas including fluorine,

a solid scavenger for fluorine of a silicon-containing or carbon-containing material in the

form of a ring about a substrate to be etched, and

a heater for said scavenger to increase its temperature to provide silicon or carbon atoms to said plasma.

23. A method for selectively etching an oxygen-containing layer of a substrate, comprising the steps of:

mounting said substrate in a vacuum chamber fitted with a dielectric shield so that said substrate is essentially parallel to said shield,

introducing a fluorine-containing etch gas to said chamber;

forming a plasma from said gas by applying a radio frequency current to a planar coil outside of said chamber and proximate to said dielectric shield, characterized by introducing a scavenger for fluorine in the form of a solid article of silicon or a silicon compound that provides silicon to said plasma.

24. A method according to claim 23 wherein said solid article of silicon is a ring about the substrate.

25. A method according to claims 23 to 24 wherein said solid article of silicon can be independently heated.

26. A method according to claims 23 to 25 wherein said solid article of silicon is adjacent to or in the plasma.
